Magnesium is an essential mineral for optimal metabolic function. Research has shown that the mineral content of magnesium in food sources is declining, and that magnesium depletion has been detected in persons with some chronic diseases. This has led to an increased awareness of proper magnesium intake and its potential therapeutic role in a number of medical conditions. Studies have shown the effectiveness of magnesium in eclampsia and preeclampsia, arrhythmia, severe asthma, and migraine. Other areas that have shown promising results include lowering the risk of metabolic syndrome, improving glucose and insulin metabolism, relieving symptoms of dysmenorrhea, and alleviating leg cramps in women who are pregnant. The use of magnesium for constipation and dyspepsia are accepted as rare indications. However, magnesium may cause adverse effects or death at high dosages. Because magnesium is excreted renally, it should be used with caution in patients with kidney disease. Food sources of magnesium include green leafy vegetables, nuts, legumes, and whole grains. (Am Fam Physician. 2009;80(2):157-162. Copyright © 2009 American Academy of Family Physicians.)

Magnesium is the fourth most abundant essential mineral in the body. It is distributed approximately one half in the bone and one half in the muscle and other soft tissues; less than one percent is in the blood. Studies estimate that 75 percent of Americans do not meet the recommended dietary allowance of magnesium, which has raised concern about the health effects of magnesium deficiency. Lifestyle factors (e.g., poor nutrition, excess alcohol intake), some medications (e.g., diuretics), and lower mineral content in commonly eaten foods (e.g., fruit, vegetables) have led to an increase in studies evaluating the potential link of magnesium deficiency to a number of diverse medical conditions, and magnesium's possible effectiveness in supplementation.

Early signs of magnesium deficiency include loss of appetite, nausea, vomiting, fatigue, and weakness. Persons may experience numbness, tingling, muscle contractions and cramps, seizures, personality changes, abnormal heart rhythms, and coronary spasms as magnesium levels decrease. Severe deficiency may lead to hypocalcemia and hypokalemia. Conditions that may lead to hypomagnesemia include poorly-controlled diabetes mellitus; chronic malabsorptive problems (e.g., Crohn disease, gluten-sensitive enteropathy, regional enteritis); medication use (e.g., diuretics, antibiotics); alcoholism; and older age (e.g., decreased absorption of magnesium, increased renal excretion).

There are challenges in diagnosing magnesium deficiency because of its distribution in the body. Magnesium is an intracellular cation and its blood concentrations may not accurately mirror magnesium status. However, reductions in normal serum magnesium concentrations (1.8 to 2.3 mg per dl. [0.74 to 0.95 mmol per L]) signify deficiency. Therefore, serum magnesium concentrations are specific, but not sensitive, to magnesium deficiency.

Magnesium homeostasis is related to calcium and potassium status, and should be evaluated in combination with these two cations. There are other methods to assess magnesium status, but the serum level is the most common and practical test in the clinical setting.

**Pharmacology**

Magnesium is the second most abundant intracellular divalent cation and is a cofactor for more than 300 metabolic reactions in the body. These processes include protein synthesis, cellular energy production and storage, cell growth and reproduction, DNA and RNA synthesis, and stabilization of mitochondrial membranes. Magnesium is one of the minerals responsible for managing bone metabolism, nerve transmission, cardiac excitability, neuromuscular...
Conduction, muscular contraction, vasomotor tone, and blood pressure. Magnesium also plays a significant role in glucose and insulin metabolism, mainly through its impact on tyrosine kinase activity, phospholipase b kinase activity, and glucose transporter protein activity. Because of these vital roles, magnesium levels may be affected by stressors to the body, such as in certain disease states. Supplementation with magnesium may have therapeutic effects in these situations.

**Uses and Effectiveness**

Magnesium has been used for numerous conditions. The most common indications are discussed here in order of most supported to least supported in the literature.

**ECLAMPSIA AND PREECLAMPSIA**

Magnesium sulfate (intravenous and intramuscular) has been shown to be relatively effective for treating eclampsia and preeclampsia, although it has been considered the standard of care for decades. In 2003, two Cochrane reviews showed that magnesium use in patients with eclampsia was superior to that of phenytoin (Dilantin) and lytic cocktail, with another study showing magnesium to be more effective than nimodipine (Nimotop). A different 2003 Cochrane review showed that 1 to 2 g of intravenous magnesium sulfate per hour reduced the risk of eclampsia in patients with preeclampsia by more than one half. The use of magnesium does not appear to have harmful effects on the mother or infant in the short term.

**ARRHYTHMIA**

A well-known use of intravenous magnesium is for correcting the uncommon ventricular tachycardia of torsade de pointes. Results of a meta-analysis suggest that 1.2 to 10 g of intravenous magnesium sulfate is also a safe and effective strategy for the acute management of rapid atrial fibrillation. A six-week randomized, double-blind crossover trial showed that oral magnesium supplementation reduced the frequency of asymptomatic ventricular arrhythmia in patients with stable congestive heart failure secondary to coronary artery disease.

**ASTHMA**

A 2000 Cochrane review of magnesium sulfate for exacerbations of acute asthma in the emergency department found that evidence does not support routine use of intravenous magnesium in all patients with acute asthma; however, it appears safe and beneficial for severe acute asthma by improving peak expiratory flow rate and forced expiratory volume in one second. In a meta-analysis of acute asthma in children, intravenous magnesium demonstrated probable benefit in moderate to severe asthma in conjunction with standard bronchodilators and steroids; however, a randomized controlled trial showed that oral magnesium added no clinical benefit to standard outpatient therapy for chronic stable asthma in adults. In a 2005 Cochrane review of inhaled magnesium sulfate in acute asthma, nebulized magnesium in addition to a beta₂ agonist were shown to improve pulmonary function and trend toward benefit in fewer hospital admissions.

**HEADACHE**

Studies have found that patients with cluster headaches and classic or common migraine, especially menstrual migraine, have low levels of magnesium. A prospective, multicenter, double-blind randomized study conducted in Germany showed that a single daily dosage of 600 mg oral trimagnesium dicitrate significantly reduced the frequency of migraine compared with placebo, whereas a lower twice daily dosage was found ineffective. For acute treatment of migraine, intravenous magnesium sulfate showed a statistically significant improvement in the treatment of all symptoms in patients with aura, or as an adjuvant therapy for associated symptoms in patients without aura.

**DYSPESIA**

Another common condition with several self-treatment options is dyspepsia, a key symptom of gastroesophageal reflux disease (GERD). Antacids are widely used...

Magnesium

Milk, reduced fat (2%) or fat free, 1 cup
Banana, raw, one medium
Avocado, California, one half cup pureed
Rice, brown, long-grained, cooked, one half cup
Peanuts, dry roasted, 1 oz
Cashews, dry roasted, 1 oz
Halibut, cooked, 3 oz

Contraindications, Adverse Effects, and Interactions

Although oral magnesium supplementation is well-tolerated, magnesium can cause gastrointestinal symptoms, including nausea, vomiting, and diarrhea. Overdose of magnesium may cause thirst, hypotension, drowsiness, muscle weakness, respiratory depression, cardiac arrhythmia, coma, and death. Concomitant use of magnesium and urinary excretion–reducing drugs, such as calcitonin, glucagon (Glucagen), and potassium-sparing diuretics, may increase serum magnesium levels, as may doxercalciferol (Hectorol). Concomitant oral intake of magnesium may influence the absorption of fluoroquinolones, aminoglycosides, bisphosphonates, calcium channel blockers, tetracyclines, and skeletal muscle relaxants. Because of this, concomitant use should be monitored or avoided when possible.

Additionally, because magnesium is cleared renally, patients with renal insufficiency (creatinine clearance of less than 30 mL per minute [0.50 mL per second]) may be at increased risk of heart block or hypermagnesemia; therefore, magnesium levels should be monitored. As with any dietary supplement, the quality of the product is important. Some magnesium products were found to contain lead.

Dosages

Oral magnesium supplementation is safe in adults when used in dosages below the upper intake level of 350 mg per day (elemental magnesium). However, higher dosages have been studied and may be used for specific medical problems. Table 1 provides selected food sources of magnesium and the amount of magnesium per serving; there is no upper intake level for dietary magnesium.
Magnesium

Magnesium is safe in children when used in dosages below the tolerable upper intake level of 65 mg per day for children one to three years of age, 110 mg per day for children four to eight years of age, and 350 mg per day for children older than eight years. Table 2 lists some common forms and dosages of magnesium.

**Bottom Line**

Magnesium is an essential mineral with evidence of effectiveness in treating eclampsia and preeclampsia, arrhythmia, severe asthma, and migraine (Table 3). The National Center for Complementary and Alternative Medicine is currently investigating the role of magnesium supplementation in mild to moderate persistent asthma. There are few studies to support wide use of magnesium for treating constipation and dyspepsia. Some of the potential indications that require further investigation include lowering the risk of metabolic syndrome, treating leg cramps in pregnant women, preventing osteoporosis, and alleviating dysmenorrhea. Diagnosis of mild to moderate magnesium deficiency is challenging because patients may be asymptomatic, and usual diagnostic testing is specific but not sensitive. Magnesium testing and supplementation should be considered in at-risk patients, especially those on diuretics, with poor nutritional intake, or with malabsorptive states. Supplementation of magnesium should generally not exceed the age-adjusted tolerable upper intake level and should be used with caution in patients with kidney dysfunction or in those taking certain medications.
